Abstract

The number of user possibilities in telecommunication systems including an internet terminal and a network for providing internet access/service is increased by introducing user-dependencies into the conversion of at least part of a Uniform Resource Locator (URL) into an IP address. This IP address defines the information to be supplied to the terminal, now user-dependently, for example location-dependently and/or time-dependently. To accomplish this, location information (Domain Name Server or DNS with location dependent content, Point-of-Presence or PoP information, terminal's IP address, terminal's phone number, user-identification, Global Positioning System or GPS information, base station controller or BSC information, area codes entered by said user) originating from the network or from the terminal and/or timing information usually originating from the network are used.
